The Heat Beneath Our Feet: Modelling Mine Energy Systems

Durham University, Department of Earth Sciences

In partnership with The Coal Authority

**Summary**
Mine geothermal energy is a viable, low-carbon heat source to warm our houses. Before installation of such mine geothermal system, it is essential to investigate the potential of local mines using predictive numerical water circulation models. This PhD project aims to investigate mine geothermal systems using numerical models to enable generic recommendations and advise on the potential productivity and risks of specific sites. The project will involve code development as well as collaboration with local and national institutes. The student will become part of a vibrant research community at Durham University, with interaction with research groups within the department of Earth Sciences, the Durham Energy Institute (DEI), and Advanced Research Computing (ARC) community across the University.

**Methodology**
This student will investigate the exchange of heat (Rodríguez & Díaz, 2009) and chemicals between mine water and the regional subsurface by developing novel and bespoke software to integrate existing and user-written thermal and chemical hydrogeological numerical models (Fig. 2). For access to mine plan data, model calibration against real systems, and incorporation of the significant local expertise, this project plans significant collaboration with the Coal Authority, the NERC Geoenergy Observatory.
across our partner organizations. Project outcomes include optimization strategies for prospected geothermal sites in the UK and elsewhere (e.g. Stanley, South Tyneside, and Blyth Port), and calculation of the effective geothermal heat capacity for onshore and North Sea near offshore asset opportunities. The onshore abandoned mine models will be further developed to address dual porosity systems in conventional former onshore/nearshore petroleum reservoirs (Beatrice in the Moray Firth; Hewett in the Southern Gas Basin).

The student will become part of the GeoNetZero CDT, which offers a multidisciplinary package of training focused around meeting the specific needs and requirements of each of our students who benefit from the combined strengths and expertise that is available across our partner organizations.

The student will benefit from a vibrant research culture in the department of Earth Sciences, in which ~70 PhD students work on various geoscience projects. In particular, Geoenergy, Environmental Science, and Computational Geoscience form major research clusters in the department of Earth Sciences, and have dedicated group meetings and seminars. The student may join the Centre for Doctoral Training in Energy for additional training activities (e.g. lectures, site visits), while the Durham Energy Institute (DEI) provides opportunities to engage in networking with other energy researchers and professionals involved with industry, policy and governance, as well as with outreach events, competitions and public lectures.

Training opportunities: data management of high-performance computing systems; numerical modelling (programming, code development, model setup, and usage); general and transferable skills.

The student is expected to attend national and international conferences to disseminate research results and to spend time away from Durham to integrate all project partners at the partner institutes.

An industrial secondment will provide valuable research experience in a commercial environment. The skills acquired through academic training and research can be applied in a different environment, while this secondment will also provide a direct link into industry, as an essential network component.

Timeline

Year 1: Training in numerical modelling, data, and knowledge exchange with regional institutes, county councils and the Coal Authority; setting up and testing of numerical models; training in project specific and transferable skills.

Year 2: Code development; application to targeted test sites; industrial secondment to enhance skill set and future employability; academic publication writing.

Year 3: Collect scientific results that will be written up in the form of several scientific publications; these will be combined with further chapters to integrate into a first draft of the PhD thesis.

Year 4: Project completion: finalizing thesis and submission of scientific manuscripts.

Training & Skills

The student will become part of the GeoNetZero CDT, which offers a multidisciplinary package of training focused around meeting the specific needs and requirements of each of our students who benefit from the combined strengths and expertise that is available across our partner organizations.
